Introduction

Spinal manipulation (SM) is defined as a “high velocity, low amplitude thrust” applied to a spinal segment.1 Many professions promote the use of adjunctive treatments such as SM for the management of non-musculoskeletal disorders.1,2,3,4 There is high-quality literature supporting the use of SM for a variety of musculoskeletal disorders, such as low back pain,5 shoulder pain,6,7 and cervical spine range of motion and pain.1 However, there is little evidence supporting its use for non-musculoskeletal conditions. The majority of peer-reviewed publications regarding the efficacy of SM in the treatment of non-musculoskeletal disorders are case studies, retrospective studies and feasibility studies.5,6 The conditions addressed range from gastrointestinal disorders such as fecal incontinence5 to neurological disorders such as Tourette syndrome.8 Although these studies report significant improvements following SM, it is important to note that the outcomes are mainly self-reported and lack randomization and/or a control group.5,6 Thus, the effectiveness of SM for the treatment of non-musculoskeletal conditions is not known due limited evidence-based support. The purpose of this study was to systematically review available literature regarding the effectiveness of spinal manipulation for the treatment of non-musculoskeletal disorders.

Methods

Pubmed, PEDro, Index to Chiropractic Literature, CINAHL and Cochrane were searched between March and April 2014 for “non-musculoskeletal,” “manipulation,” and “chiropractic” combined with “visceral,” “treatment,” “pulmonary,” “spinal,” and “endocrine.” In order to assess methodological quality, three raters applied the 10-point PEDro scale to randomized controlled trials (RCTs) meeting inclusion criteria. Studies scoring 9-10 were deemed to be of “excellent” methodological quality, studies scoring 7-8 were deemed “good” quality and studies scoring 5-6 were deemed “fair” quality. Studies scoring below 4 were deemed “poor” quality.

<th>Study</th>
<th>Intervention by Group</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Balon et al (1998)</td>
<td>20-36 treatments over 4 months</td>
<td>Morning and evening PEF: Small, non-significant increases in both treatment groups.</td>
</tr>
<tr>
<td>Pedoro=8/10</td>
<td>Active Treatment: SM in prone, side-lying, and supine in conjunction with ST therapy</td>
<td>Self-reported symptoms and use of oral corticosteroids: Decreased in both groups with no significant differences between groups</td>
</tr>
<tr>
<td>n=80</td>
<td>Simulated Treatment: STM, gentle palpation, and low-amplitude, low-velocity impulses applied to spine, paraspinal muscles, and shoulders in prone, side-lying, and supine.</td>
<td>Quality of life: Increased in both groups above MCID with no significant differences between groups.</td>
</tr>
<tr>
<td>Bronfort et al (2001)</td>
<td>20 treatments over 3 months with 1 year follow-up</td>
<td>Quality of Life Score: Significant improvement in active treatment group from baseline, with the activity scale showing the most change.</td>
</tr>
<tr>
<td>Pedoro=6/10</td>
<td>Active Treatment: SM and manipulation of sacroiliac joints with aid of table with drop mechanism.</td>
<td>Asthma Severity Rating: Significant reductions in active treatment group from baseline.</td>
</tr>
<tr>
<td>n=36</td>
<td>Sham Treatment: Light manual contact administered to the spine with no thrust but with use of drop mechanism to produce a rapid, momentary change in position.</td>
<td>Quality of Life: Increased in both groups above MCID with no significant differences between groups.</td>
</tr>
<tr>

Conclusion

There were significant improvements in some outcome measures for individuals with asthma and COPD.6,9 However, the applicability of these results is limited by the poor methodological design of the studies. This makes it impossible to attribute improvement to SM alone. Therefore, there is no conclusive evidence that supports the use of SM as a treatment for non-musculoskeletal disorders.

Relevance

Current literature supports the use of SM to treat musculoskeletal disorders.1,2,3,4 Although the evidence supporting the use of SM to treat non-musculoskeletal conditions is insufficient, some practitioners use SM as an adjunctive treatment for non-musculoskeletal disorders. It is imperative to investigate the possible benefits of SM in order to provide evidence-based treatment to individuals with non-musculoskeletal conditions. If it is found to be effective, SM may offer a conservative option for conditions such as asthma. This review illuminates the need for higher quality research when examining the effect of SM on non-musculoskeletal disorders.
