BRIEF REPORTS

Brief Reports are accounts of completed research which do not warrant regular articles or the priority handling given to Rapid Communications; however, the same standards of scientific quality apply. (Addenda are included in Brief Reports.) A Brief Report may be no longer than four printed pages and must be accompanied by an abstract.

Brans wormholes

Kamal K. Nandi and Anwarul Islam*

(Received 26 February 1996)

It is shown that three of the four Brans solutions of classes I–IV admit wormhole geometry. Two-way traversable wormholes in the Brans-Dicke theory are allowed not only for the negative values of the coupling parameter \( \omega \) \((\omega < -2)\), as concluded earlier, but also for arbitrary positive values of \( \omega \) \((\omega < \infty)\). It also follows that the scalar field \( \phi \) plays the role of exotic matter violating the weak energy condition.

\[ \square^2 \phi = \frac{8 \pi}{3+2\omega} T^\mu_{\mu}, \]

\[ R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R = -\frac{8 \pi}{\phi} T_{\mu\nu} - \frac{\omega}{\phi^2} \left[ \phi,_{\mu} \phi,_{\nu} - \frac{1}{2} g_{\mu\nu} \phi,_{\rho} \phi,_{\rho} \right] - \frac{1}{\phi} [ \phi,_{\mu},_{\nu} - g_{\mu\nu} \Box^2 \phi ], \]

where \( \Box^2 = (\phi^2),_{\rho} \) and \( T_{\mu\nu} \) is the matter energy-momentum tensor excluding the \( \phi \) field, \( \omega \) is a dimensionless coupling parameter. Brans [12] presented four classes of solutions to BDT. The general metric, in isotropic coordinates \((r, \theta, \varphi, t)\), is given by \((G = c = 1)\)

\[ ds^2 = -e^{2\omega(r)} dt^2 + e^{2\beta(r)} dr^2 + e^{2\gamma(r)} r^2 [d\theta^2 + \sin^2 \theta d\varphi^2]. \]

Brans solutions correspond to the gauge \( \beta - \nu = 0 \). Class I solutions are given by

*On leave from: Department of Mathematics, Tolaram College, Narayanganj, Dhaka, Bangladesh.
Eqs. (4) and (5) could equally well work directly with isotropic coordinates $F$ where we obtain the functions into Morris-Thorne canonical form:

$$e^{\alpha(r)} = e^{\alpha_0} \left[\frac{1 - B/r}{1 + B/r}\right]^{1/\Lambda},$$

$$e^{\beta(r)} = e^{\beta_0} \left[\frac{1 + B/r}{1 - B/r}\right]^{1/(\Lambda - C - 1)/\Lambda},$$

$$\phi(r) = \phi_0 \left[\frac{1 - B/r}{1 + B/r}\right]^{C/\Lambda},$$

$$\lambda^2 = (C + 1)^2 - C \left(1 - \frac{\omega C}{2}\right) > 0,$$

\(\alpha_0, \beta_0, B, C,\) and \(\phi_0\) are constants. The constants \(\alpha_0\) and \(\beta_0\) are determined by an asymptotic flatness condition as \(\alpha_0 = \beta_0 = 0\), while \(B\) is determined by the requirement of having Schwarzschild geometry in the weak field limit such that \(B = \lambda M/2, M > 0\) is the central mass of the configuration. Clearly \(B\) and \(\lambda\) must have the same sign.

The class I solution above is exactly the one considered in [10]. It can be easily verified that Eq. (6) of [10] is just our Eq. (7) above. The important point is that the exponents in Eqs. (4)–(6) depend on two parameters \(\omega\) and \(C\) satisfying the inequality (7). This implies that the range of \(\omega\) is dictated by the range of \(C\), which, in turn, is to be dictated by the requirements of wormhole geometry as we shall see soon.

In their analysis, Agnese and La Camera [10] use post-Newtonian values to parametrize their two exponents \(A\) and \(B\) (equivalently, our \(\omega\) and \(C\)) by a single parameter \(\gamma = (1 + \omega)/(2 + \omega)\). This procedure leads, after suitable readjustment of notations, to the equality that \(C = \gamma - 1 = 1/(\omega + 2)\), which certainly constitutes a stronger condition than the inequality (7). As a further consequence, we find \(\lambda^2 = (\omega + 1.5)/(\omega + 2) > 0\) which implies that the range \(-2 < \omega < -1.5\) must be excluded a priori as it corresponds to imaginary \(\lambda\). Therefore, it seems more logical to use the inequality (7) per se for the analysis.

In order to investigate whether a given solution represents a wormhole geometry, it is convenient to cast the metric into Morris-Thorne canonical form:

$$d\tau^2 = -e^{2\Phi(R)} dt^2 + \left[1 - \frac{b(R)}{R}\right]^{-1} dR^2 + R^2 \left[d\theta^2 + \sin^2 \theta d\varphi^2\right],$$

where \(\Phi(R)\) and \(b(R)\) are called the redshift and shape functions, respectively. These functions are required to satisfy some constraints, enumerated in [1], in order that they represent a wormhole. It is, however, important to stress that the choice of coordinates (Morris-Thorne) is purely a matter of convenience and not a physical necessity. For instance, one could equally well work directly with isotropic coordinates using the analyses of Visser [3] but the final conclusions would be the same. Redefining the radial coordinate \(r \rightarrow R\) as

$$R = r e^{\beta_0} \left[\frac{1 + B/r}{1 - B/r}\right]^{\Omega}, \quad \Omega = 1 - \frac{C + 1}{\lambda},$$

we obtain the functions \(\Phi(R)\) and \(b(R)\) as

$$\Phi(R) = \alpha_0 + \frac{1}{\lambda} \ln \left[1 - \frac{B}{r(R)}\right] - \ln \left[1 + \frac{B}{r(R)}\right],$$

$$b(R) = R \left[1 - \frac{\lambda (r^2(R) + B^2)}{r^2(R) - B^2} - 2 r(R) B (C + 1)\right].$$

The throat of the wormhole occurs at \(R = R_0\) such that \(b(R_0) = R_0\). This gives minimum allowed \(r\)-coordinate radii \(r_0^\pm\) as

$$r_0^\pm = B \left[1 - \Omega \pm \sqrt{\Omega (1 - 2\Omega)}\right].$$

The values \(R_0^\pm\) can be obtained from Eq. (9) using this \(r_0^\pm\). Noting that \(R \rightarrow \infty\) as \(r \rightarrow \infty\), we find that \(b(R)/R \rightarrow 0\) as \(R \rightarrow \infty\). Also \(b(R)/R \leq 1\) for all \(R \geq R_0\). The redshift function \(\Phi(R)\) has a singularity at \(r = r_+\). In order that a wormhole be two-way traversable, the minimum allowed values \(R_0^\pm\) must exceed \(r_+\). The extent to which this requirement is satisfied depends on specific values of \(\Omega\). Several cases are possible.

(i) \(-\infty < \Omega < 0\) \(\equiv \lambda > C + 1\). We see that \(r_0^+ > B\) while \(r_0^- < B\). Hence a real, positive throat radius \(R_0^+\) exists only when \(r = r_+\). The function \(\Phi(R)\) is also nonsingular for \(R > R_0^+ > 0\) and it is finite everywhere. We therefore have a two-way traversable wormhole. On the other hand, if \(r = r_0^- < B\), the corresponding value \(R_0^-\) is imaginary and hence does not represent a wormhole.

(ii) \(\Omega = 0\) \(\equiv \lambda = C + 1\). This gives a minimum allowed radius \(r_0^+ = B\) and the function \(\Phi(R)\) is singular at the corresponding radius \(R_0^- = 4B\). Thus we obtain a non-Schwarzschild one-way wormhole since \(C \neq 0\) and the scalar field \(\phi\) is present. The choice \(\Omega = 0\) indicates the absence of the \(\Phi\) field and we have what is known as the one-way Schwarzschild wormhole.

(iii) \(0 < \Omega < 2\) \(\equiv \lambda > C + 1\). In this case, \(r_0^\pm\) and hence \(R_0^\pm\) are imaginary. Hence, no wormhole can be constructed.

(iv) \(2 \leq \Omega < \infty\) If \(\lambda\) assumes a positive sign and so does \(B\), then \(r_0^\pm\) and \(R_0^\pm\) both become negative and hence wormholes are not possible. Let \(\lambda\) assume a negative sign so that \(B = -B', B' > 0\). Then, from Eq. (12), we get \(r_0^+ > B', r_0^- < B'\). The function \(\Phi\) has no horizon at \(r = r_0^\pm\) and is finite for \(r > r_0^\pm\) and we have a two-way wormhole with a corresponding throat radius \(R = R_0^-\). But if \(r = r_0^+\), then \(\Phi(R)\) is undefined, and we cannot have a wormhole. The case \(\Omega = 2\) corresponds to case (ii) above.

Summing up, we see that two-way wormhole solutions are allowed only in the ranges \(-\infty < \Omega < 0\) and \(2 < \Omega < \infty\) (with \(\lambda\) negative, \(\lambda = -\lambda', \lambda' > 0\)). Let us write out \(\Omega\) in terms of \(\omega\) and \(C\) explicitly:

$$\Omega = 1 - \frac{C + 1}{\lambda} = 1 - \frac{C + 1}{\left[(C + 1)^2 - C(1 - \omega C/2)\right]^{1/2}}.$$

It is evident that \((C + 1)\) and \(\lambda\) must have the same sign for \(\Omega < 0\). Suppose both have minus signs. Then, \(C + 1 = -t, t > 0\), say. The following inequality must hold:

$$t > \left[t^2 + (1 + t)[1 + (\omega/2)(1 + t)]\right]^{1/2} \Rightarrow (t + 1)\omega < -2.$$

It is possible to choose \(t\) in such a way that \(\omega\) may take on any arbitrary value in the open interval \((-2, 0)\). Suppose again that both \((C + 1)\) and \(\lambda\) have plus signs. Then, \(C + 1 = s, s > 0\), say. The following must hold:
In the present case, it can be seen that $a < b$, then $\omega < -2 \Rightarrow -\infty < \omega < -\infty$. (b) If $1 < s < \infty$, take $s = 1, b = 0$. Then, $b, \omega < 2$. In the limit $b \to 0$, we have $\omega \to \infty$. In other words, $\omega$ can take on arbitrary positive values if $a$ and $b$ are appropriately chosen. For $2 < \Omega < \infty$, we must have $(C+1) > \frac{\Lambda}{2}$ and we can find $\omega < \infty$ from the same analysis as above.

The combined energy density of the gravitational (second-order derivatives of $g_{\mu\nu}$) and scalar ($\phi$) field $(T_\phi + T_\phi)_{\mu\nu}$ is obtained by computing the Einstein tensor $G_{\mu\nu}$ such that

$$G_{\mu\nu} = \frac{1}{8\phi} (T_\phi + T_\phi)_{\mu\nu} = \frac{1}{R^2} \frac{db}{dR}. \quad (14)$$

From Eq. (11), we obtain

$$\frac{db}{dR} = -24r^2B^2 \left[ \Omega(2-\Omega) \right]. \quad (15)$$

If $\Omega < 0$ or $\Omega > 2$, then $db/dR < 0$. This implies that, with $\phi$ everywhere non-negative, $G_{\mu\nu} < 0$. This shows that the scalar field $\phi$ plays the role of exotic matter at the wormhole throat. The same conclusion was reached also in [10].

The axially symmetric embedded surface $z = z(R)$ shaping the wormhole’s spatial geometry is obtained from

$$\frac{dz}{dR} = \pm \left[ \frac{R}{b(R)} - 1 \right]^{1/2}. \quad (16)$$

For a coordinate-independent description of wormhole physics, one may use proper length $l$ instead of $R$ such that

$$l = \pm \int_{R_0}^{R} \frac{dR}{\left[ 1 - b(R)/R \right]^{1/2}}. \quad (17)$$

In the present case,

$$l = \pm \int_{r_0}^{r} e^{\beta(r)} dr. \quad (18)$$

This integral is not integrable in a closed form. Nonetheless, it can be seen that $l \to \pm \infty$ as $r \to \pm \infty$.

Class II solutions are given by

$$\alpha(r) = a_0 - \frac{2}{\Lambda} \arctan \left( \frac{r}{B} \right), \quad (19)$$

$$\beta(r) = \beta_0 - \frac{2(C+1)}{\Lambda} \arctan \left( \frac{r}{B} \right) - \ln \left( \frac{r^2}{r^2 + B^2} \right), \quad (20)$$

$$\phi(r) = \phi_0 e^{(2C+1)/\Lambda \arctan(r/B)}, \quad (21)$$

$$\Lambda^2 = C \left( 1 - \frac{\omega C}{2} \right) - (C+1)^2 > 0. \quad (22)$$

The constants $a_0$ and $\beta_0$ are determined by using an asymptotic flatness condition and the constant $B$ is determined by the weak field condition as follows:

$$a_0 = -\frac{\pi}{\Lambda}, \quad \beta_0 = \frac{\pi(C+1)}{\Lambda}, \quad B = \frac{\Lambda M}{2}. \quad (23)$$

where $M > 0$ is the central mass of the configuration. The inequality (22) fixes the range of $\omega; C \geq -1 \Rightarrow \omega < -2$, or, $C < -1 \Rightarrow -2 < \omega < -3/2$. The sign of $\Lambda$ is left undetermined. Under the radial coordinate transformation $r \to R$

$$R = r \left( 1 + \frac{B^2}{r^2} \right) \exp \left[ 1 - \frac{2}{\pi} \arctan \left( \frac{r}{B} \right) \right] \beta_0, \quad (24)$$

class II solutions yield

$$\Phi(R) = -\frac{\pi}{\Lambda} + \frac{2}{\Lambda} \arctan \left( \frac{r(R)}{B} \right). \quad (25)$$

$$b(R) = R \left[ 1 - \frac{1 + 2B}{r^2 + B^2} \left( \frac{r(R)(C+1)}{\Lambda} - B \right) \right]. \quad (26)$$

Once again, $R \to \infty$ as $r \to \infty$ and all the conditions for a two-way wormhole are satisfied by the above $\Phi(R)$ and $b(R)$. The function $\Phi(R)$ has no horizon, is finite everywhere, and $\Phi(R) \to 0$ as $R \to \infty$. The $r$ radii of the throat are given by

$$r_0 = \frac{B\beta_0}{\pi} \left[ 1 \pm (1 + \beta_0/\pi^2)^{1/2} \right]. \quad (27)$$

As usual, putting these values in Eq. (24), we can find $R_0 \pm$. Notice that finite positive values of $r$ (except $r = 0$) correspond to finite positive values of $R$. Thus we require that $r_0 > 0$ so that we can have $R_0 > 0$. Rewriting Eq. (27) as $r_0 = pM(1 + C)$, where $p > 0$ is an arbitrary real number, we find that the range $C > -1$ allows two-way wormhole solutions since it ensures $r_0 > 0$. In the same way, $r_0 = -qM(1 + C)$ where $q > 0$ is any arbitrary real number and $C < -1$ implies a finite positive $R_0^+$ for the wormhole throat radius in the range $-2 < \omega < -3/2$.

It can be verified that

$$\frac{db}{dR} \bigg|_{R \to R_0^{-}} = -1 \quad (28)$$

and hence there occurs a WEC violation. The flaring-out condition $d^2z/dR^2 > 0$ is also satisfied, since it can be verified that

$$\frac{d^2z}{dR^2} \bigg|_{R \to R_0^{-}} = \frac{1}{R_0^+}. \quad (29)$$

The proper length $l$ is given by

$$l = \pm e^{\beta_0} \int_{r_0}^{r} e^{\beta(r)} dr = \pm e^{\beta_0} \left[ (r - r_0^{-}) + \cdots \right]. \quad (30)$$

Again, $R \to \pm \infty \Rightarrow l \to \pm \infty$ as $r \to \pm \infty$.

Class III solutions are given by

$$\alpha(r) = a_0 - \frac{r}{B}, \quad (31)$$

$$\beta(r) = \beta_0 - \ln \left( \frac{r^2}{r^2 + B^2} \right), \quad (32)$$

$$\phi(r) = \phi_0 e^{-\left( C/\Lambda B \right)}, \quad (33)$$

$$C = -\frac{1 \pm \sqrt{-2\omega + 3}}{\omega + 2}. \quad (34)$$

The redshift and shape functions are
\[
\Phi(R) = \alpha_0 - r(R)/B, \quad (35)
\]

\[
b(R) = R \left[ 1 - \left( \frac{C + 1}{B} \right)^2 \right], \quad (36)
\]

where

\[
R = r^{-1/2} e^{\left( \beta_0 + \frac{C + 1}{B} r \right)}. \quad (37)
\]

Here, too, \( R \rightarrow \infty \) as \( r \rightarrow 0 \) but \( b(R)/R \rightarrow 0 \) as \( R \rightarrow \infty \). Also \( \Phi(R) \rightarrow \infty \) as \( R \rightarrow \infty \). Asymptotic flatness condition is also not satisfied by this solution. Therefore, there is no question of any wormhole geometry in this case.

Class IV solutions are

\[
\alpha(r) = \alpha_0 - 1/Br, \quad (38)
\]

\[
\beta(r) = R_0 + (C + 1)/Br, \quad (39)
\]

\[
\phi = \phi_0 e^{-(C/2)}, \quad (40)
\]

\[
C = -1 \pm \sqrt{-2\omega - 3}/\omega + 2. \quad (41)
\]

Usual asymptotic flatness and weak field conditions fix \( \alpha_0, \beta_0, \) and \( B \) as

\[
\alpha_0 = \beta_0 = 0, \quad B = 1/M > 0. \quad (42)
\]

The functions are

\[
\Phi(R) = -\alpha_0 - 1/Br(R), \quad (43)
\]

\[
b(R) = R \left[ 1 - \left( \frac{1}{Br(R)} \right)^2 \right], \quad (44)
\]

\[
R = r \exp\left( \frac{C + 1}{Br} \right). \quad (45)
\]

The wormhole throat occurs at

\[
r = r_0 = (C + 1)/B \Rightarrow R = R_0 (C + 1)/B e^l. \quad (46)
\]

It can be verified from Eq. (41) that \( (C + 1)>0 \) only if \( \omega > -2 \). No wormhole is possible if \( -2 < \omega < -3/2 \) or \( \omega > 3/2 \), since \( C + 1 \) is either negative or imaginary.

The proper length is given by

\[
l = \pm \int_{r_0}^{\infty} \exp\left( \frac{C + 1}{Br} \right) dr. \quad (47)
\]

One can see that if \( r \rightarrow \pm \infty \), then \( R \rightarrow \pm \infty \) and \( l \rightarrow \pm \infty \). It can be verified that all the conditions of a two-way wormhole including the flaring-out condition are satisfied. The peculiarity of this solution is that

\[
\frac{db}{dR} = -\left( \frac{C + 1}{Br} \right)^2 < 0, \quad (48)
\]

and hence \( G_{00} < 0 \) for all finite nonzero values of \( r \) (and, of course, \( R \)). This implies that the entire wormhole, and not only the throat, is made up of exotic material.

The special case \( C = -1 \) is not of interest as it corresponds to a flat spatial section.

It was shown in the foregoing that three out of the four types of Brans solutions give rise to a two-way traversable wormhole geometry provided the constants are chosen appropriately. The restriction \( \omega < -2 \) need no longer be stringently maintained, for, as we have seen, \( \omega \) can also take on positive values in the context of two-way wormholes. This result extends the scope for the feasibility of wormhole scenarios even to the regime of ordinary observations. For example, laser-ranging probes and observations on binary systems put a lower limit of \( \omega > 500 - 600 \) [13–15]. However, there occurs a violation of the WEC at the wormhole throat even for \( \omega < -\infty \) (class I solutions), but, unlike in [10], the range of \( \omega \) (or \( \gamma \)) alone does not cause it. The positive, real values of the throat radii \( r_0^+ \), (or \( R_0^\pm \)) containing both \( \omega \) and \( C \) are actually responsible for the WEC violation, as we have just seen. Only in class IV solutions do we see that WEC is violated for all values of \( r \).

A search for wormhole geometry in BDT amounts to an investigation of the extent to which the scalar field \( \phi \) does play the role of exotic matter required for WEC violation. Researches into the existence of matter having negative energy density (or, negative mass) are not new. It was Bondi [16] who initiated the work and, in recent years, we have a number of investigations into the question of negative energy [17–20]. Interestingly, Pollard and Dunning-Davies [20] show that no contradictions arise if negative mass is introduced into Newton’s laws of motion.

One of us (A.I.) wishes to thank the Indian Council for Cultural Relations (ICCR), Azad Bhawan, Indraprastha, New Delhi, for financial support through an Exchange Program of the Government of India.
